## School

- [School Name](Grand Valley State University)

## 1. Introduction

This project is to analyze the citation network of ArXiv papers. We will use the data from two specific file "data\oai-arxiv-metadata-hash-abstracts-2019-03-01.json" and "data\internal-references-pdfotext.json" to get the citation information of the papers using python code to clean data and create neo4j network. We will then use the data to analyze the citation network of ArXiv papers.

## 2. Data Description

- I collected this data using the ArXiv API. The data is in JSON format and contains the metadata of the papers. The data includes the title, authors, abstract, and references of the papers. The data is stored in two files: "data\oai-arxiv-metadata-hash-abstracts-2019-03-01.json" and "data\internal-references-pdfotext.json". After having the needed data, I used Python to clean the data and create a Neo4j network.
- By watching the neo4j graph database using the command `MATCH (n) RETURN n`, I can see the citation network of the ArXiv papers. The nodes represent the papers, and category and the edges represent the citations between the papers and category between them. There are two different kinds of nodes in the graph: `Paper` and `Categorie`. The papers are connected to the categories by the `CATEGORIZED` relationship. The papers are connected to each other by the `CITES` relationship.
- The `Paper` nodes have 9 attributes including `elementId` - the element Id of the paper, `id` - the identifier of the paper in the database, `abstract_md5` - the MD5 hash of the abstract of the paper, `authors` - the list of authors of the paper, `doi` - the Digital Object Identifier of the paper, `idAxv` - the identifier of the paper in the ArXiv database, `report_no` - the report number of the paper, `submitter` - the submitter of the paper, `title` - the title of the paper. The `Category` nodes have 3 attributes including `elementId` - the element Id of the category, `id` - the identifier of the category in neo4j graph, `category` - the name of the category.
- The `CATEGORIZED` relationship has 2 attributes including `elementId` - the element Id of the relationship, `id` - the identifier of the relationship in the database. The `CITES` relationship has 2 attributes including `elementId` - the element Id of the relationship, `id` - the identifier of the relationship in the database.

There are 313 nodes and 667 relationships by reviewing the neo4j graph database.

Graph Screenshot

## 3. Analysis

### 3.1 Network Metrics

Composites:

- The average number of cited for each paper is : 0.783
- This shows that each paper in the dataset is cited approximately 0.783 times by other papers. This suggests that not all papers are cited frequently, and some papers are not be cited at all.

Graph Screenshot

- The number of paper for each category:

Graph Screenshot

Category Name	Number of Papers
hep-ph	95

V. Dolotin, A. Morozov and Sh. Shakirov	2
Kimiko Yamada	2
Guowu Meng	2
Serhiy E. Samokhvalov	2

Maximums:

- The table shows that the most popular category is "hep-ph" with 95 papers, followed by "hep-th" with 80 papers. The least popular categories are "math.GN" and "cs.DM" with only 1 paper each.

- The most important paper is ""Stringy Instantons at Orbifold Singularities" with being cited 3 times.
  - The max papers by an author is 2, and there are 14 authors with 2 papers.  
Density:
  - The density of the network is  $217(\text{number of CITES links}) / 38226(\text{total number of PAPER nodes pairs}) = 0.005$  which is very low. This means that the network is very sparse. That is make sense in citation networks because not all papers are cited by all other papers and vice versa.
- //Node pair metrics

## 3.2 Node pair metrics

- The most cocitation:

Graph Screenshot

- We picked the top 4 cocitation pairs to show the most cocitation pairs since the table is too long to show all of them.

Paper1	Paper2	CoCitationCount
"Strong Phase and $D^0$ - $\bar{D}^0$ mixing at BES-III"	"D-\bar{D} mixing and rare D decays in the Littlest Higgs model with non-unitarity matrix"	2
"Marginal Solutions for the Superstring"	"Analytic solutions for marginal deformations in open superstring field theory"	2
"Numerical Evaluation of Six-Photon Amplitudes"	"Direct extraction of one-loop integral coefficients"	2
"Improved Measurement of the Positive Muon Lifetime and Determination of the Rate of Muon Capture in Hydrogen Gas and Determination of the Proton's Pseudoscalar Coupling $g_P$ "	"Measurement of the Fermi Constant"	2

- The table is make sense since the most cocitation pairs are the pairs that are related to each other. For example, the first pair is about the mixing of D mesons and the second pair is about the marginal solutions for the superstring.
- The most bibliographic coupling:

Graph Screenshot

Paper1	Paper2	BibliographicCouplingCount
"Implication of the $D^0$ Width Difference On CP-Violation in $D^0$ -anti- $D^0$ Mixing and CP Violation in $D^0$ vs anti- $D^0$ to $K^*$ "	"n $D^0$ - $\bar{D}^0$ Mixing" (+-) $K$ (-+) Decays"	2
"Marginal deformations in string field theory"	"Real analytic solutions for marginal deformations in open superstring field theory"	2
"On-Shell Methods in Perturbative QCD"	"One-loop phi-MHV amplitudes using the unitarity bootstrap"	2
"Muon Physics: A Pillar of the Standard Model"	"Electroweak Radiative Corrections to Muon Capture"	2

- From the cocitation and bibliographic coupling tables, we can see that the most cocitation and bibliographic coupling pairs are related to each other. On the one hand, the number of cocitation and bibliographic coupling pairs is very low compared to the number of papers. This is because not all papers are cited by all other papers and vice versa which is common in citation networks.

### 3.3 Nodes metrics

1. The paper that has the highest degree (using neuler):

Graph Screenshot

- The result show that a paper with title "Moriond QCD 2007 - Theory Summary" has the most informaiton about other papers with 5 citations.

2. The paper that has the highest betweenness centrality (using neuler):

Graph Screenshot

- The result show that a paper with title "Moriond QCD 2007 - Theory Summary" has the highest betweenness centrality with the score of 24. This means that this paper is the most important paper in the network since it has the most shortest paths between other papers.

3. The paper that has the highest closeness centrality (using neuler):

Graph Screenshot

- The result show that all papers have the same closeness score of 1. This means that each paper cites or is cited by all other papers in the network. This is common in citation networks since all papers are connected to each other through citations.

4. The paper that has the highest eigenvector centrality (using neuler):

Graph Screenshot

- The result show that the papers with the following titles "Marginal Solutions for the Superstring", "Analytic solutions for marginal deformations in open superstring field theory", "Direct extraction of one-loop integral coefficients", "Numerical Evaluation of Six-Photon Amplitudes" have the highest eigenvector centrality with the score of 0.45. This means that these papers are the most influence and prestige papers in the network since they are cited by other important papers.

5. Papers with highest custerling coefficient (using neuler):

Graph Screenshot

Graph Screenshot

Graph Screenshot

- The result show that there are 30 papers with the highest clustering coefficient of 1. This means that these papers are in the same cluster and they are connected to each other through citations. This is common in citation networks since papers in the same categories are usually cited by each other.

## 4. Limitaion:

- The limitation of this analysis is that the neu4j graph is not big enough to fully show 4000 papers which mean that the result may not be accurate. In addition, the analysis is only based on the data in the graph database, so it may not be able to show the full picture of the citation network.

## 5. Conclusion:

- In conclusion, by using many data analysis techniques and tool, we can analyze the citation network to find the most important papers, the most popular categories, the most cocitation and bibliographic coupling pairs, and the most influence papers. This analysis can help us to understand the structure of the citation network and the relationship between papers in the network. However, the limitation of the analysis is that the graph database is not big enough to fully show the citation network and we may not be able to get the full picture of the network. In the further work, we will remodify the althorithm to collect datas that able to show the full picture of the network.
